# 1 Packet Sniffing and Spoofing Lab

## 1.1 Task 1.1: Sniffing Packets

### 1.1.1 Task 1.1A

Wireshark is the most popular sniffing tool, and it is easy to use. We will use it throughout the entire lab. However, it is difficult to use Wireshark as a building block to construct other tools. We will use Scapy for that purpose. The objective of this task is to learn how to use Scapy to do packet sniffing in Python programs. A sample code is provided in the following:

```
#!/usr/bin/python
from scapy.all import *

def print_pkt(pkt):
    pkt.show()

pkt = sniff(filter='icmp',prn=print_pkt)

if __name__ == "__main__":
    # execute only if run as a script
    print_pkt(pkt)
```

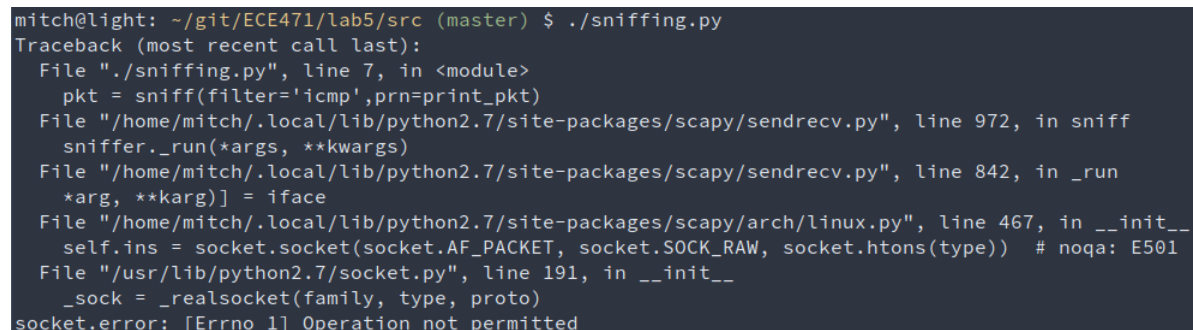

This code is placed into a file named sniffing.py and made executable with the following command

```
$ sudo chown +x sniffing.py
```

The code can then be ran with the following command

```
$ ./sniffing.py
```

The output after running as root is as follows:

```
mitch@light: ~/git/ECE471/lab5/src (master) $ ./sniffing.py
Traceback (most recent call last):
  File "./sniffing.py", line 7, in <module>
    pkt = sniff(filter='icmp',prn=print_pkt)
  File "/home/mitch/.local/lib/python2.7/site-packages/scapy/sendrecv.py", line 972, in sniff

    *arg, **karg]] = iface
  File "/home/mitch/.local/lib/python2.7/site-packages/scapy/arch/linux.py", line 467, in __init__
    self.ins = socket.socket(socket.AF_PACKET, socket.SOCK_RAW, socket.htons(type)) # noqa: E501
  File "/usr/lib/python2.7/socket.py", line 191, in __init__
    _sock = _realsocket(family, type, proto)
socket.error: [Errno 1] Operation not permitted
```

Figure 1: Running the sniffing program without root

Looks like we need to utilize root to be able to run this script!

After running the script as root, nothing gets shown because there has been no packets sent yet.

### 1.1.2 Task 1.1b

Usually, when we sniff packets, we are only interested certain types of packets. We can do that by setting filters in sniffing. Scapy's filter use the BPF (Berkeley Packet Filter) syntax; you can find the BPF manual from the Internet. Please set the following filters and demonstrate your sniffer program again (each filter should be set separately):

1. Capture only the ICMP packet
2. Capture any TCP packet that comes from a particular IP and with a destination port number 23.
3. Capture packets comes from or to go to a particular subnet. You can pick any subnet, such as 128.230.0.0/16; you should not pick the subnet that your VM is attached to.

```
1. pkt = sniff(filter="icmp")
```

To only pull icmp packets, you can use the filter option to force only icmp packets to show up.

```
2. pkt = sniff(filter="tcp and port 23 and host 66.35.250.151")
```

To pull up only tcp packets on a certain port from a certain host, the preceding filter can be applied. To chain together multiple filters, you can simply put the keyword 'and' between the filters. 'tcp', 'port 23', 'host 66.35.250.151'.

```
3. pkt = sniff(filter="host 128.230.0.0/16")
```

To gather packets on a subnet, the above filter is applied!

## 1.2 Task 1.2: Spoofing ICMP Packets

As a packet spoofing tool, Scapy allows us to set the fields of IP packets to arbitrary values. The objective of this task is to spoof IP packets with an arbitrary source IP address. We will spoof ICMP echo request packets, and send them to another VM on the same network. We will use Wireshark to observe whether our request will be accepted by the receiver. If it is accepted, an echo reply packet will be sent to the spoofed IP address. The following code shows an example of how to spoof an ICMP packets.

```
>>> from scapy.all import
>>> a = IP()
>>> a.dst = '10.0.2.3'
>>> b = ICMP()
>>> p = a/b
>>> send(p)
```

```
.
```

Sent 1 packets.

In the code above, Line  $\hat{A}$  creates an IP object from the IP class; a class attribute is defined for each IP header field. We can use `ls(a)` or `ls(IP)` to see all the attribute names/values. We can also use `a.show()` and `IP.show()` to do the same. Line  $\hat{A}$  shows how to set the destination IP address field. If a field is not set, a default value will be used.

Line  $\hat{A}$  creates an ICMP object. The default type is echo request. In Line  $\tilde{A}$ , we stack `a` and `b` together to form a new object. The `/` operator is overloaded by the IP class, so it no longer represents division; instead, it means adding `b` as the payload field of `a` and modifying the fields of `a` accordingly. As a result, we get a new object that represent an ICMP packet. We can now send out this packet using `send()` in Line  $\hat{A}$ . Please make any necessary change to the sample code, and then demonstrate that you can spoof an ICMP echo request packet with an arbitrary source IP address.

And here is the results of sniffing the packet using the program from Task1.1a.

```
###[ Ethernet ]###
dst      = 3c:37:86:f2:c4:56
src      = d0:ab:d5:bb:40:f9
type     = IPv4
###[ IP ]###
version  = 4
ihl      = 5
tos      = 0x0
len      = 28
id       = 1
flags    =
frag     = 0
ttl      = 64
proto    = icmp
chksum   = 0xad33
src      = 192.168.1.2
dst      = 10.0.2.3
\options \
###[ ICMP ]###
type     = echo-request
code     = 0
chksum   = 0xf7ff
id       = 0x0
seq      = 0x0
```

This shows that we can utilize `scapy` to do exactly what it should do.

### 1.3 Task 1.4: Sniffing and-then Spoofing (Extra Credit)

In this task, you will combine the sniffing and spoofing techniques to implement the following sniff-and- then-spoof program. You need two VMs on the same LAN. From VM A, you ping an IP X. This will generate an ICMP echo request packet. If X is alive, the ping program will

receive an echo reply, and print out the response. Your sniff-and-then-spoof program runs on VM B, which monitors the LAN through packet sniffing. Whenever it sees an ICMP echo request, regardless of what the target IP address is, your program should immediately send out an echo reply using the packet spoofing technique. Therefore, regardless of whether machine X is alive or not, the ping program will always receive a reply, indicating that X is alive. You need to use Scapy to do this task. In your report, you need to provide evidence to demonstrate that your technique works.

## 2 ARPCache Poisoning Attack Lab

### 2.1 Task 2.1: ARP Cache Poisoning

The objective of this task is to use packet spoofing to launch an ARP cache poisoning attack on a target, such that when two victim machines A and B try to communicate with each other, their packets will be intercepted by the attacker, who can make changes to the packets, and can thus become the man in the middle between A and B. This is called Man-In-The-Middle (MITM) attack. In this lab, we use ARP cache poisoning to conduct an MITM attack.

The following code skeleton shows how to construct an ARP packet using Scapy.

```
#!/usr/bin/python3
from scapy.all import *
E = Ether()
A = ARP()
pkt = E/A
sendp(pkt)
```

The above program constructs and sends an ARP packet. Please set necessary attribute names/values to define your own ARP packet. We can use `ls(ARP)` to see the attribute names of the ARP class. If a field is not set, a default value will be used (see the third column of the output):

```
>>> from scapy.all import *
>>> ls(ARP)
<data about ARP>
```

In this task, we have three VMs, A, B, and M. We would like to attack A's ARP cache, such that the following results is achieved in A's ARP cache.

B's IP address --> M's MAC address

To execute this lab, the following script is used inside a file named 'VagrantFile'

```
# -*- mode: ruby -*-
# vi: set ft=ruby :

# Vagrant multi-machine sample setup
```

```

Vagrant.configure("2") do |config|
  config.vm.define :m do |m|
    m.vm.box = "hashicorp/precise64"
    m.vm.network :private_network, ip: "10.0.0.10"
    m.vm.hostname = "m"
  end

  config.vm.define :a do |a|
    a.vm.box = "hashicorp/precise64"
    a.vm.network :private_network, ip: "10.0.0.11"
    a.vm.hostname = "a"
  end

  config.vm.define :b do |b|
    b.vm.box = "hashicorp/precise64"
    b.vm.network :private_network, ip: "10.0.0.12"
    b.vm.hostname = "b"
  end
end

```

To populate the virtual machines, run the following command in the directory that the VagrantFile exists in:

```
$ vagrant up
```

This command will provision 3 machines each with host name 'm', 'a', 'b'.

You can then ssh into these virtual machines with the following command:

```
$ vagrant ssh [m|a|b]
```

Where you choose whether to ssh into m, a, or b.
